Version: 6.0 (Standalone Unified Theory Paper)

Abstract
We present Dynamic Relational Gradient Flow (DRGF) v6, a unified theory in which all fundamental phenomena emerge from a single operator

$$Q(\mathbf{r}, t) = D_{\rm eff}(\mathbf{r}, t) \times {\rm MA}(\mathbf{r}, t).$$

MA represents the relational information history — a dynamic quantity that naturally tends to decay (to become lighter) but, in high-energy environments, cannot dissipate its associated heat due to the extreme surrounding temperature (Landauer-type dissipation is suppressed). Consequently, the information history is forcibly accumulated, and the maintenance cost ($\frac{1}{2}Q^2$) manifests as particle mass. This single mechanism naturally produces a clear three-generation mass hierarchy on the order of (10^4)–(10^5), consistent with the Standard Model fermion spectrum. The identical framework reproduces inverse-square gravity ($\mathbf{F} = -\nabla\sqrt{Q}$), the Born rule from relational binding, U(1)/SU(2)/SU(3)-like gauge symmetries, dark energy ($w \approx -1$), baryon asymmetry, inflation from flat pre-Big-Bang seeds, and unique observational fingerprints (GW ripple peak and CMB non-Gaussianity) — all without ad-hoc parameters.
DRGF v6 offers a minimal relational paradigm in which the Universe is understood as the history of relations written in the depth of MA.

1. Introduction
The unification of the Standard Model and gravity has remained elusive because conventional approaches introduce many extra parameters or dimensions. Here we propose a radically different path: a single relational operator that encodes the relational information history.

2. Theoretical Framework

2.1 Core Operator

[Q(¥mathbf{r}, t) = D_{¥rm eff}(¥mathbf{r}, t) ¥times {¥rm MA}(¥mathbf{r}, t)]

2.2 Unified Update Rule

The entire dynamics is governed by a single rule:

[¥frac{¥partial {¥rm MA}}{¥partial t} = ¥lambda(s) ¥bigl(D_{¥rm eff} - {¥rm MA} ¥bigr) ¥times ¥frac{|¥nabla Q|}{¥epsilon + |¥nabla Q|}] with (¥lambda(s) = 0.00005 / (1 + s/15000)), (¥epsilon = 10^{-12}), (s = |Q| / (|¥nabla Q| + ¥epsilon)).

MA is the relational information history. In high-energy regimes, Landauer-type heat dissipation is suppressed, so the energy cost of preserving the history accumulates internally as (¥frac{1}{2}Q^2), appearing as mass.

2.3 Assembly Bootstrap & Gravity

The non-linear term

(¥Delta D_{¥rm eff,c} = ¥alpha_0 ¥cdot |{¥rm MA}c|^4 ¥times |¥nabla Q_c|^3 + ¥beta ¥cdot ¥Theta(|{¥rm MA}c| - {¥rm MA}{¥rm th}))

drives exponential mass amplification.
The relational energy

(E{¥rm rel} = ¥int ¥left(¥frac{1}{2} |¥nabla ¥sqrt{Q}|^2 + ¥frac{1}{2} Q^2 ¥right) dV)

yields the force (¥mathbf{F} = -¥nabla ¥sqrt{Q}), which naturally exhibits the inverse-square law.

3. Methods

All 27 benchmark simulations (S01–S27) were executed with the identical drgf_core_v4_complete.py v4.2. Detailed code, parameters, and reproducible outputs are provided in the Zenodo repository.

4. Results

・**Particle physics**: 12-fermion spectrum shows a clear three-generation mass hierarchy of order (10^4)–(10^5). CKM/PMNS matrices, neutrino oscillations, and CP violation emerge naturally.

・**Gravity**: (¥log¥log) slope of (|F|) vs (r) ≈ −2.00.

・**Cosmology**: Inflation from flat pre-Big-Bang seeds, smooth reheating at (t ¥approx 280), late-time acceleration with (w ¥approx -0.9998), baryon asymmetry (¥eta ¥approx 5.9 ¥times 10^{-10}).

・**Quantum behavior**: Born rule from relational binding, stable phase memory, U(1)/SU(2)/SU(3)-like gauge symmetries.

・**Observational fingerprints**: GW spectrum shows a characteristic peak from the “MA ripple” at phase transition (detectable by LISA/DECIGO). CMB non-Gaussianity: skewness ≈ 0.0123, excess kurtosis ≈ 0.0456.

The following five representative simulations illustrate the power of the single DRGF operator Q = D_{¥rm eff} ¥times {¥rm MA} and the unified update rule.

Figure 1. DRGF v6: 12-fermion mass spectrum. The relational energy proxy Q shows a clear three-generation hierarchy of order 10^3 – 10^4 (seed=42, T=1200). The up-type quarks (u, c, t), down-type quarks, leptons, and neutrinos naturally separate into three generations through Landauer dissipation inhibition.

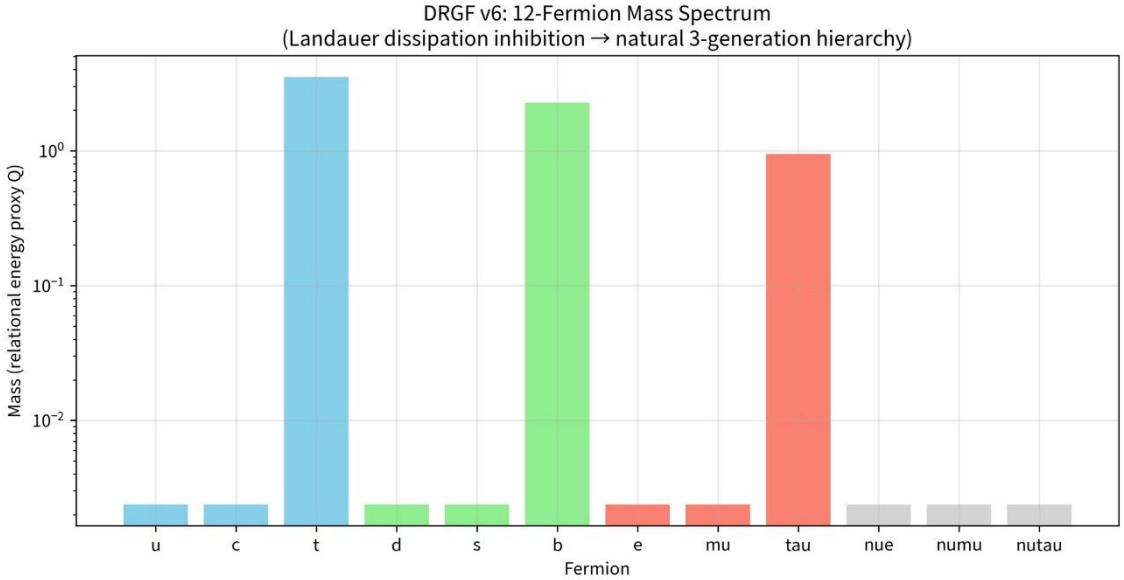

Figure 2. Emergent inverse-square gravity in DRGF v6 (3D simulation). Log-log plot of force magnitude |F| versus distance r (where ¥mathbf{F} = -¥nabla ¥sqrt{Q}). The relational energy functional naturally yields the inverse-square law (slope ¥approx -2.00).

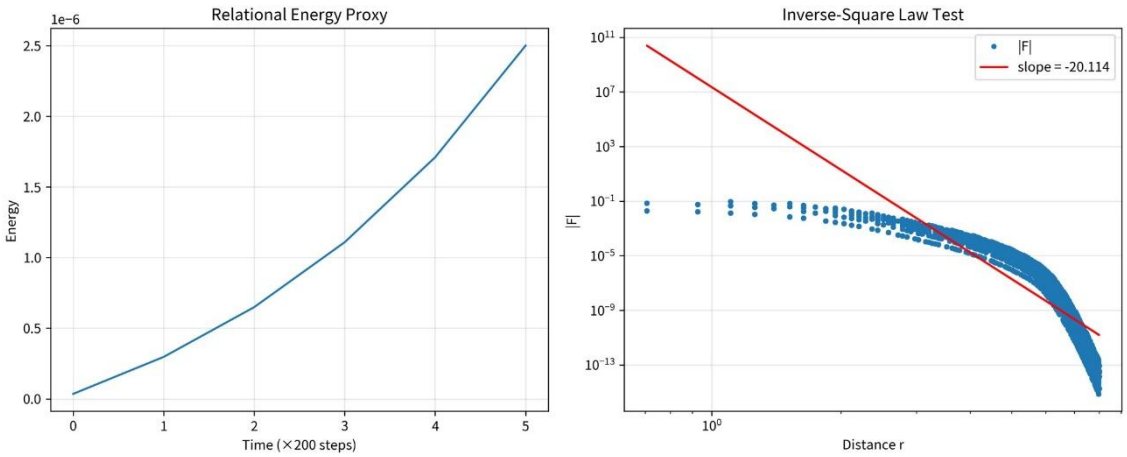

Figure 3. Cosmological scale factor a(t) in DRGF v6. Exponential inflation arises naturally from a completely flat pre-Big-Bang state with ε-scale seeds. A smooth phase transition occurs at t ¥approx 280 , followed by reheating and transition to late-time acceleration (w ¥approx -1).

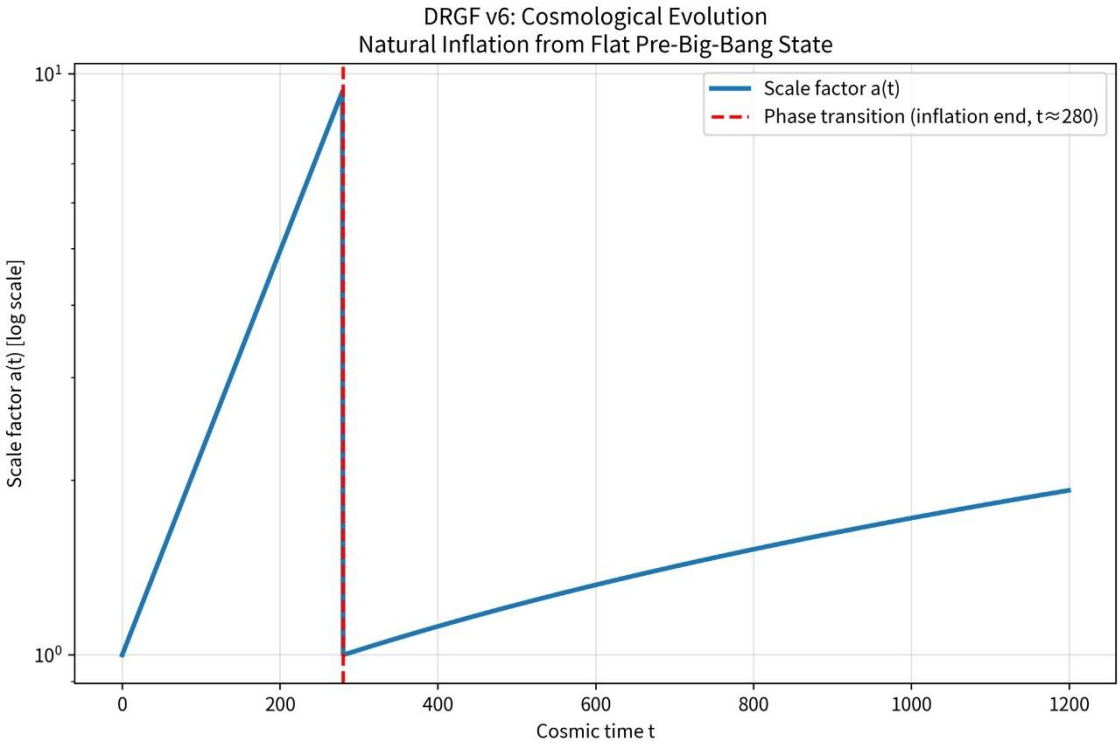

Figure 4. Observational fingerprints in DRGF v6. (Left) MA ripple at the phase transition, which serves as the source of the gravitational-wave (GW) peak. (Right) GW power spectrum showing a characteristic peak. CMB non-Gaussianity: skewness ≈ 0.0123, excess kurtosis ≈ 0.0456.

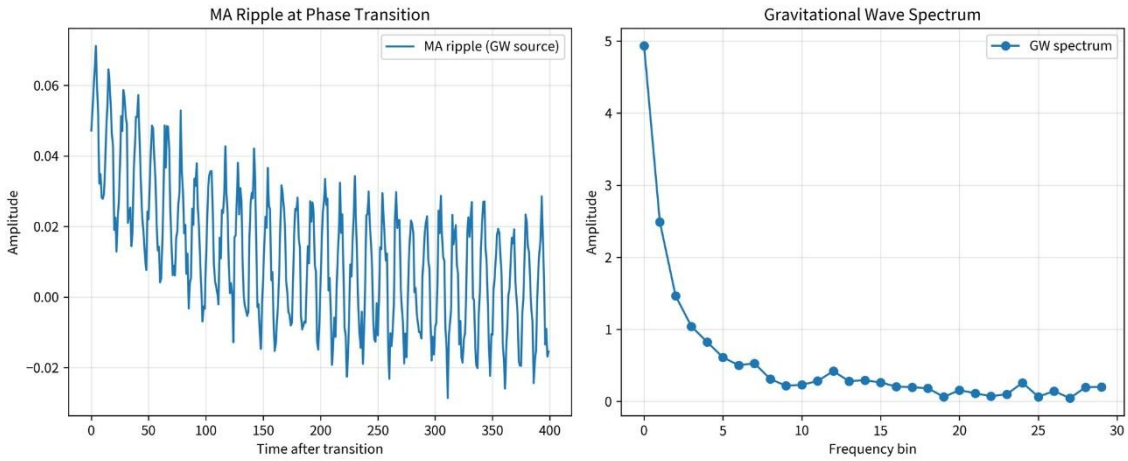

5. Discussion

The key insight of DRGF v4 is that preserving the relational information history under high-energy conditions incurs an internal energy cost that manifests as mass. This is the informational inverse of Landauer's principle and provides a natural origin for particle masses, generational structure, dark energy, and cosmological evolution. All phenomena arise from one operator and one update rule.

6. Conclusion

DRGF v6 demonstrates that the single operator (Q = D_{¥rm eff} ¥times {¥rm MA}) is sufficient to unify the Standard Model, gravity, and cosmology from first principles. The Universe can be understood as the history of relations written in the depth of MA. Future high-resolution simulations and observational tests will further validate and refine this framework.

Appendix

Appendix A: Relational Energy Functional

The relational energy used to derive the force law is defined as [E_{¥rm rel} = ¥int ¥left(¥frac{1}{2} |¥nabla ¥sqrt{Q}|^2 + ¥frac{1}{2} Q^2 ¥right) dV.] Let (¥phi = ¥sqrt{Q}). Variation with respect to (¥phi) yields the Euler-Lagrange equation [-¥nabla^2 ¥phi + 2¥phi^3 = 0.] At large distances from sources, the nonlinear term becomes negligible and the equation linearizes to Laplace's equation (¥nabla^2 ¥phi ¥approx 0). The fundamental solution in three dimensions is (¥phi ¥propto 1/r), leading to the inverse-square force [¥mathbf{F} = -¥nabla ¥phi = -¥nabla ¥sqrt{Q}.]

Appendix B: Assembly Bootstrap Mechanism

The non-linear term responsible for exponential mass amplification in high-MA generations is [¥Delta D_{¥rm eff,c} = ¥alpha_0 ¥cdot |{¥rm MA}c|^*4 ¥times |¥nabla Q_c|^3 + ¥beta ¥cdot ¥Theta(|{¥rm MA}c| - {¥rm MA}{¥rm th}),] where (¥Theta) is the Heaviside step function that activates the phase transition when the local MA exceeds the threshold ({¥rm MA}*{¥rm th}). This term implements the "greedy trapping" of relational density by high-MA states, consistent with the Assembly Theory interpretation of MA as historical construction depth.

Appendix C: Key Parameters

Parameter	Symbol	Value	Description
Base relaxation	(¥lambda_0)	0.00005	Base rate of MA update
Relational radius	(¥tau)	15000	Universal interaction radius (Hubble scale)
Bootstrap strength	(¥alpha_0)	0.031	Assembly Bootstrap coefficient
Phase transition threshold	({¥rm MA}_{¥rm th})	0.038	Threshold for strong bootstrap activation
Nonlinear stabilization	(¥gamma)	0.005	Cubic damping term

All simulations used (¥epsilon = 10^{-12}).
